Adding Address Tools to Your Experience

Last Updated: 04/19/2021

Read this guide to learn how to use address tools in your experience.

Introduction

Nike's address tools provide valuable address management functionality.

- Use the **Address Validation** service before the consumer places their order to ensure their packages will be shipped to a deliverable address.
- Call the **Address Geocoding** service to turn an address into longitude and latitude coordinates in order to call other Nike APIs that require geocodes, such as [Fulfillment Offerings](#).

Address Validation

Ensure a shipping address is deliverable

Ensure a billing address is valid

Validate a consumer-supplied address with the [Validate Address](#) service. This endpoint can validate any type of address such as shipping and billing addresses.

This service calls a third party vendor to validate the address passed in the request against an address database. The service response contains a `verificationCode`, `score`, and an address. Based on the quality of the address match, the service returns either the original address or a corrected one. See the table below to understand how the `verificationCode` and `score` work together to determine what actions the consumer needs to take next.

Table 1: Address Validator Verification Codes and Scores with Next Steps

Verification Code	Score	Consumer needs to
VERIFIED	95 or greater	Address provided by the consumer is verified and is returned in the response. No further action is required by the consumer.
VERIFIED	less than 95	Address provided by the consumer is missing information and a recommended address is returned in the response. Consumer needs to review the recommended address and decide to accept it or retry with a different address.
PARTIALLY_VERIFIED, UNVERIFIED, AMBIGUOUS, CONFLICT, REVERTED	any	Address provided by the consumer could not be verified and is returned in the response. Consumer needs to correct the address and retry.

TIP: The third party address validation service has a 512 character limit restriction on each address field and a 1024 character limit for the entire address. The client should truncate characters in any address field exceeding the field limit or address limit before making the request.

See the [Address Validation Service](#) page for more information on request and response field mappings between the Address Validator API and the third party.

Listed below is a sample **Address Validate** POST request URI. This is a synchronous endpoint and is not JWT-protected:

```
https://api.nike.com/location/address_validator/v1
```

Address Geocoding

Turn an address into latitude and longitude coordinates

Need to call an API that requires the consumer’s latitude and longitude location coordinates but you only have the consumer’s address? Call the **Get Geocodes from Address API** passing address information as query parameters.

Get geographic coordinates from an address

The [Geocoding API](#) allows you to exchange an address for latitude and longitude geo coordinates. This service is not JWT-protected.

Table 2: Request Query Parameters for the Get Geocodes from Address Endpoint

Parameter Name	Description	Required?	Example
country	2-alpha character ISO 3166 country code	Required	US
address1	String	Optional	One Bowerman Drive
address2	String	Optional	1st Floor
address3	String	Optional	Suite 100
city	String	Optional	Beaverton
state	ISO 3166-2 subdivision code. 2-alpha character ISO 3166-2 state code for US addresses	Optional	OR
county	String. Holds regional data for non-US addresses	Optional	Washington
postalCode	String. Both 5 digit and 5 digit-4 digit formats are supported for US addresses	Optional	97005

Tip: If address values contain spaces, enclose the value in quotes for example, `filter=address1("1 Bowerman Drive")`.

Sample [Get Geocodes from Address](#) cURL GET request:

```
curl -X GET "https://api.nike.com/buy/geocodes/v1?filter=country(US)&filter=address1("1 Bowerman Drive")&filter=city("Beaverton")&filter=state(OR)&filter=postalCode(97005)" -H "accept: application/json; charset=UTF-8"
```

A successful 200 response contains the `country` passed in the request, `latitude`, `longitude` and in some cases, `geoDistance`. `geoDistance` represents the accuracy radius in meters between the geocode coordinates and the physical location.

API Quick Reference

Address Validator

- [Validate Address](#)

Address Geocoding

- [Get Geocodes \(coordinates\) from Address](#)
